

# Levels of Living and Poverty Patterns: A District-Wise Analysis for India

SILADITYA CHAUDHURI, NIVEDITA GUPTA

Most of the contemporary studies of level of living and poverty concentrate only on state-level averages. In view of the growing divergence both between and within the states, disaggregated studies are necessary for accurate identification of the critical areas calling for policy intervention. In the National Sample Survey Organisation's Consumer Expenditure Survey held in 2004-05, the sample design had taken districts as strata in both the rural and urban sectors, which makes it possible to get unbiased estimates of parameters at the district level.

This paper presents a profile of levels of living, poverty and inequality for all the districts of the 20 major states of India. An attempt has also been made to map poverty in the districts to examine their spatial disparity within and across the states.

Numerous studies have been made in recent years on the trends of poverty, inequality and level of living in Indian states during the 1990s. Some have highlighted the reduction in poverty (Sundaram and Tendulkar 2003; Bhanumurthy and Mitra 2004) while some others have expressed anguish over the rising economic inequality (Deaton and Dreze 2002; Sen and Himanshu 2004; Krishna 2004).

## 1 Introduction

There is a common feeling that although there has been some overall improvement in the average level of living of people across the majority of states, those which were already on a better footing could reap the advantages of the economic reform in the 1990s and experience fast growth, while there was no tangible improvement for the poorest few. Again, the rural-urban expenditure gap, believed to have widened over time, needs meticulous scrutiny. There is a strong indication that the improvement in the level of living might not have been distributed well and certain pockets of the states might have remained impoverished in spite of their overall growth. Thus, dealing merely with state-level aggregates may not reveal the true extent of disparity prevailing and there has been a serious dearth of studies on these issues at the sub-state level. It is also necessary to examine how far the assumption of states as homogeneous units for socio-economic studies, is tenable.

Very few studies have been attempted any district level analysis. Again, most of them were based on a small segment of the country. Sastry (2003) had discussed the feasibility of using the National Sample Survey (NSS) Consumer Expenditure Survey (CES) data for district-level poverty estimates in its entirety based on the NSS 1999-2000 (55th round) survey. But the main bottleneck that refrained researchers from generating sub-state or district-level estimates from NSS data was the nature of sampling design.<sup>1</sup> It was only in the 61st round survey of NSS (2004-05) that the sampling design defined rural and urban parts of districts as strata for selection of sample villages and urban blocks respectively. This has paved the way for generating unbiased estimates of important socio-economic parameters at the district-level adequately supported by the sample design.

The paper is divided into five sections. In Section 2 an ogive analysis<sup>2</sup> depicts the wide interstate disparity in population distribution over the all-India monthly per capita consumption expenditure (MPCE) classes, which is perfectly adequate for country level analysis or for comparison among states. But use of state-level percentile MPCE classes<sup>3</sup> has been suggested

The authors are grateful to an anonymous referee of this journal for comments on an earlier version. The organisation to which the authors belong is in no way responsible for the observations and comments drawn in this paper.

(Per cent distribution of population over different expenditure classes)

additionally for more realistic analysis at state/sub-state-level with adequate representation across the MPCE percentile classes. Section 3 discusses the state-level estimates of major parameters for subsequent comparison with the corresponding estimates at the district level. Average MPCE<sup>4</sup>, head count ratio (HCR) using state-specific poverty lines,<sup>5</sup> Lorenz ratio using state-level percentile classes (LR-S)<sup>6</sup> and the relative standard errors (RSES) of average MPCE were the major parameters under consideration. However, the main focus of the study is on district-level estimates of the parameters and their level of divergence, which is discussed in Section 4 with four sub-sections. The first sub-section discusses the methodology of obtaining district-level estimates, followed by broad observations on the salient features of detail district estimates. In the third sub-section, a graphical presentation of the district-level pattern in terms of the HCR has been made to map the pockets of poverty across the country. The last sub-section examines the spatial disparity among the districts both within and across the states. Section 5 summarises the findings, discusses the limitations of the present exercise and explores the ways of improvement.

## 2 Distribution of Population in States over Expenditure Classes – Ogive Analysis

In the NSS 61st round survey reports, detail analysis was carried out by classifying the population into 12 percentile classes (at 5%, 10%, 20%, ..., 80%, 90%, 95%) of MPCE at the all-India level, separately for the rural and urban sectors, which was necessary for the analysis of survey results at the country level or for the comparisons among states against the same set of MPCE classes. An ogive analysis has been attempted here to study the divergence of the distribution in the states from the *all-India MPCE percentile class* distribution.

In Figures 1R and 1U (p 96) the ogives for some of the most poor/rich states are plotted against the central ogive for the country as a whole. For the remaining states, the ogives lie somewhere within the band. If we look at the extreme end percentile classes in rural India (Figure 1R), we find that for the bottom 10 percentile class of the country (with MPCE of Rs 270 or less), the share of population varied widely from state to state. Orissa had more than 30% of its people in this class as against less than 1% of population in a state like Punjab. At the other end of the spectrum, was the top 10 percentile class all-India (MPCE more than Rs 890), where Kerala and Punjab had about a third of their population as against less than 4% in Chhattisgarh and Orissa.

Again, an extremely lopsided distribution of sample households in different states over the all-India MPCE percentile classes is evident from Tables 1R and 1U. In rural Punjab only nine sample households belonged to the bottom 10 percentile class. Such low sample sizes at state-level in these all-India percentile classes would certainly affect the reliability of the estimates at MPCE class-level even for the state-level analysis.

In urban India, the situation was no better either (see Figure 1U or Table 1U). Bihar and Orissa were the two most impoverished

states with more than 25% of their population in the bottom 10 percentile class of the country (i.e., MPCE less than Rs 395) whereas Punjab and Himachal Pradesh had less than 2% of their people in this category. In terms of distribution of sample households over the MPCE classes, Himachal Pradesh had as few as six samples in the bottom 10 percentile class.

Thus, although all-India MPCE percentile classes are useful for the interstate comparisons, yet they often affect the estimates and their reliability at the state x MPCE class level due to inadequate sample size. For district-level estimates the problem gets more serious, especially when we find some of the districts not having any sample in one or more all-India MPCE percentile classes, as evident from Table 2 (p 96).

Out of 508 rural districts of the 20 major states of the country, more than a third of the districts did not have any sample in the first (i.e., the bottom 5%) MPCE class. Again out of 510 urban districts, as many as 149 districts did not have any sample in the top five percentile classes. In all there were 425 instances in rural India and 558 in the urban, where a district did not have any representation in an all-India MPCE percentile class. In some of the extreme cases (as given in Table 3, p 96), we found that only four samples in a particular district were in the bottom 50 percentile class. However, as in the case of Ambala in Haryana and Pathanamthitta in Kerala, such a problem can be addressed through the use of state-level percentile classes for analysis at state/district-level as indicated in Table 3.

Therefore, it appears appropriate that, in addition to *all-India MPCE classes* used for country-level analysis and interstate comparison, state-level MPCE percentile classes be used for

**Table 1R: Population Share of Poorest and Richest States in the All-India Percentile Classes (Rural)**

States	Population in the Bottom 10 Percentile Classes (i.e., MPCE ≤ Rs 270)	Population in the Top 10 Percentile Classes (i.e., MPCE ≥ Rs 890)
Orissa	31.1% (926) *	3.7% (265)
Chhattisgarh	24.1% (325)	3.3% (182)
Kerala	2.3% (50)	37.5% (1598)
Punjab	0.5% (9)	31.9% (1005)

\* The figures in brackets give the number of sample households falling in the respective percentile classes.

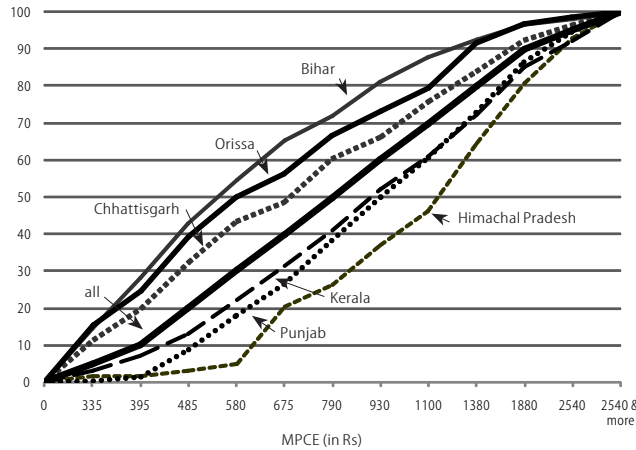

**Table 1U: Population Share of Poorest and Richest States in the All-India Percentile Classes (Urban)**

States	Population in the Bottom 10 Percentile Classes (i.e., MPCE ≤ Rs 395)	Population in the Top 10 Percentile Classes (i.e., MPCE ≥ Rs 1880)
Bihar	28.2% (436) *	3.4% (48)
Orissa	24.6% (344)	3.2% (58)
Punjab	1.3% (45)	13.6% (280)
Himachal Pradesh	1.7% (6)	19.1% (99)

\* The figures in brackets give the number of sample households falling in the respective percentile classes.

**Figure 10: Ogive Analysis – Urban**

(Per cent distribution of population over different expenditure classes)

obtaining more reliable estimates at state x MPCE classes for the purpose of state or sub-state level analysis. For better comparability with the official results, an identical composition (i.e., 5%, 10%, 20%, etc) of state-level percentile classes has been advocated. Accordingly, the lower and upper limits of the state-level MPCE percentile classes have been derived for the 20 major states of the country for 2004-05, separately for the rural and the urban sectors (see Table A1.R and A1.U at Annexure, p 101).

**3 Overview of State-Level Estimates of Major Parameters**

Before moving on to the district-level estimates of the parameters let us have a quick look at the corresponding state-level estimates for the 20 major states of India including the three newly created states of Jharkhand, Chhattisgarh and Uttarakhand. More than 98% of the country’s rural population and about 94% of urban population reside in these 20 states. In Table 4 (p 97), a summary of state-level estimates of the parameters – average MPCE, the HCR and Lorenz ratio – has been given which together reflect the level of living. The RSE of average MPCE estimates have also been indicated. These would be useful for comparison with the corresponding estimates at the district level. For J&K, state-level estimates suffer from certain limitations owing to non-coverage of some of the districts<sup>7</sup> of the state in the NSS survey (2004-05).

In rural India the average MPCE was the lowest in Orissa (Rs 399) and the highest in Kerala (Rs 1,013). The RSE of average state-level MPCE was found to be low (less than 5%) except for rural Haryana. All-India rural HCR was around 28%. States like Punjab and J&K had less than 10% poor while Orissa and Jharkhand, each had more than 46% of their population below the respective poverty lines. For better comparability with the districts, the level of inequality in the states has been calculated using state-level percentile classes (L.R-s) although these do not vary much from the usual LR using all-India percentile classes. Inequality was found to be low in states like Assam (0.1964) and Bihar (0.2054) where average level of living was also low. On the other hand, the two best average MPCE states in the rural part, i.e., Kerala (Rs 1,013) and Haryana (Rs 863) were the two most unequal states with L.R-s 0.3748 and 0.3347, respectively. Thus in

rural India there was some indication of a trade-off between prosperity and inequality at state level.

Average urban MPCE again varied from Rs 696 and Rs 757 in Bihar and Orissa, respectively, to more than Rs 1,300 in Punjab and Himachal Pradesh (HP). Orissa had the highest urban poverty (45%) while it was less than 4% in HP and Assam. The most critical position was that of urban Chhattisgarh which had the highest inequality (0.4308), coupled with high poverty (42.2%) and low average MPCE. Urban inequality was also high in Kerala (0.4307) and Punjab (0.3936), the states which were placed at the third (Rs 1,291) and second (Rs 1,326) highest position respectively, in terms of average per capita expenditure. Thus, the high urban inequality in the better-off states as well as in some of the poor states made the issue more complex. Another notable feature was that, in half of the states the RSE of MPCE estimates was more than 5% in the urban sector.

**4 Level of Living in Indian Districts**

This section first discusses some of the methodological issues.

**4.1 Methodological Issues**

As already indicated, NSS 61st round survey (2004-05) enabled district-level estimation mainly through its stratification scheme. The survey design followed the usual stratified multi-stage sampling scheme but in this particular round districts were taken as strata for selection of first stage units (FSU) in both the rural and urban sectors. Further sub-stratification was done within the strata (i.e., districts) as per the following rule:

If “r” be the sample size allocated for a rural stratum, the number of sub-strata formed was “r/2”. The villages within a district as per frame were first arranged in ascending order of population and each sub-stratum comprised of a group of villages having more or less equal population. In urban sector the sub-stratification scheme was almost similar to that of rural area. Here the towns in a district were arranged in ascending order of population. Finally, the FSUs were drawn following Probability Proportional to Size with Replacement (PPSWR) scheme in rural area and Simple Random Sampling Without Replacement (SRSWOR)

**Table 2: Instances of No Sample Representation**

MPCE Classes (Rs)	Number of Districts Not Having Any Sample in All-India MPCE Percentile Class												
	0-5	5-10	10-20	20-30	30-40	40-50	50-60	60-70	70-80	80-90	90-95	95+ Total Cases	
Rural	162	114	51	22	8	3	3	3	0	4	25	30	425
Urban	96	49	13	11	22	19	23	28	34	33	81	149	558

**Table 3: Sample Households in the Districts Falling in All-India and State Percentile Classes**

State	District	Item	Using All-India Percentile Classes		Using State Specific Percentile Classes	
			Bottom 50 Percentile Class	Top 50 Percentile Class	Bottom 50 Percentile Class	Top 50 Percentile Class
(1)	(2)	(3)	(4)	(5)	(6)	(7)
Rural Haryana	Ambala	Population share	3.9%	96.1%	38.9%	61.1%
		No of samples	4	76	28	52
Kerala	Pathanamthitta	Population share	5.2%	94.8%	45.1%	54.9%
		No of samples	4	156	51	109
Urban Himachal Pradesh	Bilaspur	Population share	13.8%	86.2%	38.7%	61.3%
		No of samples	7	33	18	22

in urban area. This was a significant deviation in the sampling design from the earlier NSS rounds.<sup>8</sup>

In the NSS 1999-2000 survey, i.e., the previous large sample CES, the selection of first stage units in the rural area was done using the circular systematic sampling scheme taking districts as strata while in the urban area, selection was done following

**Table 4: State Level Estimates of Average MPCE, Headcount Ratio and Lorenz Ratio in 2004-05**

State	Rural					Urban				
	% of All-India Population	Average MPCE (Rs)	RSE of Average MPCE	% Poor	Lorenz Ratio-S	% of All-India Population	Average MPCE (Rs)	RSE of Average MPCE	% Poor	Lorenz Ratio-S
Andhra Pradesh	7.4	586	1.50	10.5	0.2896	7.5	1,019	3.72	27.4	0.3693

Uttarakhand	0.9	647	4.49	40.7	0.2859	0.8	978	6.0	36.5	0.364
West Bengal	8.1	562	2.02	28.4	0.2696	7.8	1,124	3.1	13.5	0.3786
All India	100.0	559	0.54	28.3	-	100.0	1,052	1.14	25.6	-

For calculating per cent poor (HCR) state-specific poverty lines released by Planning Commission have been used and for Lorenz Ratio (LR-S) state-specific percentile classes as given in the Annexure.

srsWOR where strata were formed using town size class within NSS regions, and not with districts as strata. Thus, while in the 1990-2000 survey, districts were taken as homogeneous units in the rural sector, in NSS (2004-05) high population variability at the district-level was assumed and was taken care of through sub-stratification into similar size villages expected to have more homogeneous consumption pattern. Even the second stage stratifications of CES (2004-05) were different from that of CES (1999-2000).

The RSE<sup>9</sup> of average MPCE, has been calculated using sub-sample variations of estimates at sub-stratum level, as given in the official estimation procedure of NSS 61st round.<sup>10</sup> Sastry (2003) had worked out average RSE of MPCE for different MPCE classes at district level for the 1999-2000 survey and then probably combined them to obtain district-level average RSE without presenting the district-wise MPCE estimates. But the average RSEs given there were not strictly comparable to the RSEs computed here for the reasons stated in the previous paragraph.

#### 4.2 Estimates for All Districts within the States

In order to get a good understanding of the level of living prevailing in the districts, we need to study the estimates for all the major parameters (average level of living, poverty and inequality) together and not in isolation from one another. The district-level estimates of the parameters for all the districts of 20 major states of India have been derived and presented in Table A2 (p 102) in the annexure. The two sets of estimates for rural and urban sectors are placed side by side to indicate the magnitude of the rural-urban divide even at

the sub-state (i.e., district) level. For measurement of HCR at the district-level, state-specific poverty lines have been used. The state-level MPCE percentile classes have been utilised for calculating Lorenz ratio for the districts. The number of sample observations and the estimated RSE of average MPCE have been given to indicate the reliability and robustness of the estimates.

Although the parameters (i.e., average MPCE, HCR and LR-S) have been estimated for all the districts of the 20 major states of India, no attempt has been made to analyse in detail the pattern of these parameters in each of the districts, rather the figures have been allowed to speak for themselves. Nevertheless, certain broad features emerged.

(a) There were perceptible differences between the rural and urban areas of many districts in terms of one or more parameters. A district with excellent performance in either average MPCE or in percentage poor or in Lorenz ratio in one sector often failed to put up a matching record in the other sector.

(b) In some of the states, a majority of the districts had MPCE much below the state-level MPCE and only a few very high MPCE districts were responsible for pulling up the state averages.

(c) The number of sample observations was too small for many of the districts in the urban sector. Often low sample size or high RSE of the estimates restricted us from making conclusive remarks about the estimates. This was particularly true for urban Orissa and Chhattisgarh.

(d) The range of RSE for the district-level estimates of MPCE is summarised in Table 5 (p 98).

About 25% of the districts yielded RSE lower than 5%, and 77% of districts had less than 10% RSE in the rural areas. In the urban areas the corresponding figures were 12% and 41%, respectively. Thus, about one-fourth of the rural districts and more than half of the urban districts had RSE of MPCE more than 10%, which was often due to low sample size.

(e) In spite of incidents of high RSE of MPCE estimates, it is indeed useful to look at these natural estimates at the district-level supported by the sample design. These estimates can be used for further refinement through "model assisted" as well as "model independent" procedures. A Generalised Regression Estimate (greg)<sup>11</sup> method may be one of the simplest ways of improving upon these initial estimates.

(f) In both the sectors, there were some districts in almost all the states for which within district inequality (Lorenz ratio) was higher than the inequality at state level.

#### 4.3 Mapping of Poverty in Indian Districts

The district-level HCR, an absolute measure comparable across the country irrespective of any exogenous influences, has been portrayed graphically here to summarise the performances of the

districts in terms of the most tangible measurement of poverty. This exercise enables easy identification of critically poor pockets, that demand more focused attention. It also depicts the variability in the poverty ratio across the districts.

The critically high HCR districts were concentrated in states like Orissa, Chhattisgarh, Jharkhand, Bihar, Madhya Pradesh and eastern Uttar Pradesh. On the other hand, almost zero-poverty districts were mainly from HP, J&K, Gujarat and Assam. Again, in the rural sector, more than half of about 500 districts had HCR of 30% or less, while in 16% of districts HCR was 50% or more.

In case of the urban sector, high poverty districts were clustered in the states of Orissa, Chhattisgarh, Karnataka, Maharashtra, Bihar, etc. Low urban poverty districts were found mainly in states like Haryana, HP, J&K and Punjab in the north and Assam in the east. Also, the percentage of urban districts in the higher ranges of HCR was always greater than that in its rural counterpart and in about 22% of districts urban HCR was more than 50%. This highlights the grim urban poverty scenario that needs to be reckoned with due importance.

**4.4 State-wise Best and Worst Districts**

A summary of best and worst districts within each state in terms of average MPCE or poverty (HCR) is presented here to indicate the spatial disparity among the districts within and across the states.

From the Table 7R (p 99) we observe the following:

(a) While in rural India at the state level the average MPCE of the best state (Kerala) was 2.5 times that of the worst (Orissa), within state divergence in the level of living was no less alarming. In Chhattisgarh, Gujarat and Karnataka, the average MPCE for the best district was almost thrice that of the worst. The gap between best and worst districts was narrow only in case of two eastern states, i.e., Assam and West Bengal.

(b) Among all the rural districts of the 20 major states of the country, Gurgaon, Haryana (Rs 1,559) had the highest average level of living while Dantewada, Chhattisgarh (Rs 218) had the lowest. The gap between the two was too wide even in spite of interstate price differences.

(c) In Chhattisgarh, Orissa, MP, Jharkhand and Bihar there were districts, some of which had average MPCE around Rs 300 or less (i.e., Rs 10 per capita per day). Barring

MP and Chhattisgarh, in all these states the average MPCE even in the best districts was less than Rs 600 (Rs 20 per capita per day). Such low level of living all over a state is a matter of grave concern. In contrast, in rich states like Kerala, Haryana and HP, the average MPCE in any of the districts was not less than Rs 600.

(d) In terms of rural poverty, the scenario was quite intriguing. In the states of Bihar, Chhattisgarh, Gujarat, Jharkhand, MP, Orissa and UP, in a number of districts, the HCR was as high as 75% or more. On the other hand, in states like Assam, Gujarat, Himachal Pradesh, J&K and Karnataka, in one or more districts there was “zero poverty”.

**Table 5: Frequency of Districts by RSE Level**

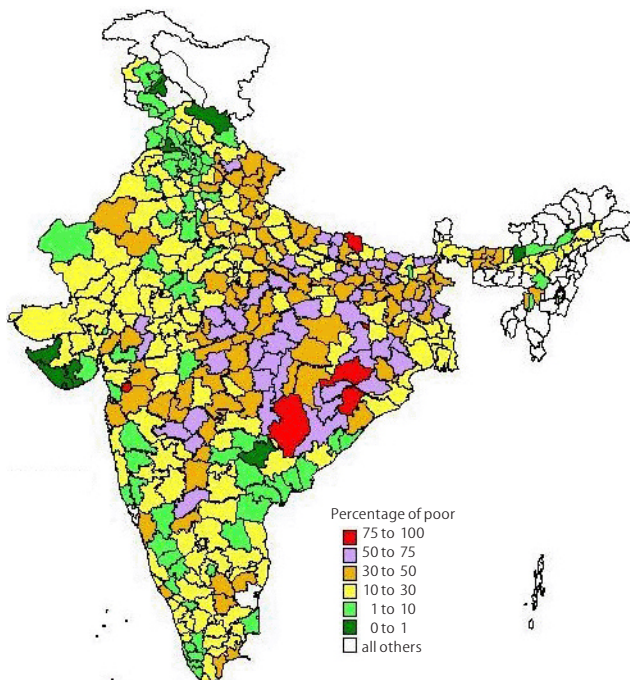

RSE Level (%)	Frequency of Districts	
	Rural	Urban
< 5	129(25.4)	59(11.6)
5-10	262(51.6)	148(29.0)
10-20	98(19.3)	213(41.8)
20 and above	19(3.7)	90(17.6)
Total	508	510

The figures in brackets indicate percentage occurrences.

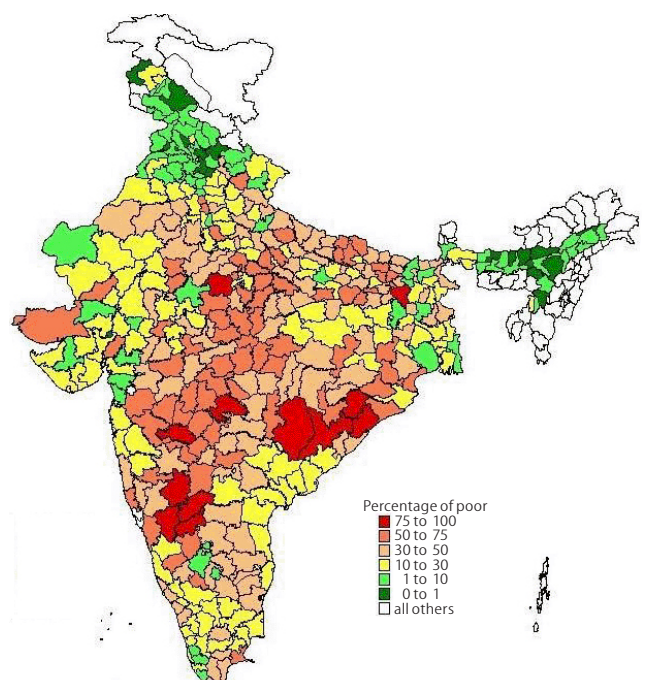

**Table 6: Percentage Distribution of Districts over Different HCR Classes**

% Poor (HCR)	Percentage of Districts	
	Rural	Urban
Less than 1.0	2.5	3.2
1.0-10.0	17.4	15.5
10.0-30.0	39.8	29.1
30.0-50.0	24.4	30.0
50.0-75.0	13.8	20.0
75.0-100.0	2.1	2.3

For calculating % poor (HCR) state-specific poverty lines released by Planning Commission have been used.

(e) In Gujarat we found the district Dangs, which had been the poorest rural district of the country with 88% population below state-specific poverty line, while in the same state at least three districts Junagadh, Jamnagar and Porbandar had “zero poverty”.

In urban India the intra-state disparity in terms of MPCE and poverty was of higher dimension as compared to the interstate differences. Table 7U reveals the following:

(a) While the best state average MPCE (HP, Rs 1,390) was just about double the worst (Bihar, Rs 696), the disparity among the

districts within each state was far more glaring. In at least four states, i.e., Haryana, Chhattisgarh, Karnataka and Gujarat the average MPCE for the best district had been more than four times that of the worst. In four other states (MP, Maharashtra, UP and AP) the ratio of best and worst was still more than three. Only in Himachal Pradesh and J&K, the ratio was found to be less than two.

(b) For the country as a whole, Kurukshetra, Haryana was the best MPCE district (Rs 2,851) followed by Gandhinagar, Gujarat (Rs 2,422). At the other extreme was Banka, Bihar with lowest average MPCE of Rs 355, followed by Raichur, Karnataka (Rs 407).

(c) In HP, the average MPCE in was more than Rs 1,000, while in none of the districts of urban Bihar the average MPCE could reach that level.

(d) The urban poverty scenario was more grim. Most abject poverty could be found in Gajapati, Orissa with more than 90% people below the state poverty line. The second poorest urban district was Raichur (88.6%) in Karnataka. In four other states, i.e., Bihar, Chhattisgarh, Maharashtra and Madhya Pradesh there were one or more districts with HCR higher than 75%.

(e) At the other extreme were the districts with “zero” or “near-zero” HCR in the states of Assam, Haryana, HP, J&K and Punjab. Assam and J&K had less than 15% poverty in all of their districts.

From the discussion above, it is apparent that the sub-state level estimates are extremely useful in identifying pockets of impoverishment or prosperity across the length and the breadth of the country.

Even in a state like Gujarat with commendable growth performance in terms of level of living, poverty or inequality, we find a district like Dangs, which was among the most critically poor regions of India in 2004-05. Such incidents would have escaped our attention had we restricted ourselves to state-level averages only. The study also revealed major indications of polarisation in the level of living within and across the states.

## 5 Conclusions

This paper attempts to cater to the long felt need for generation of district-level estimates of major socio-economic parameters to facilitate more focused analysis. The results obtained strongly indicate the serious limitations of seeing the "state" as a homogeneous socio-economic unit for poverty or inequality analysis. In fact, it is felt that state-level aggregates may often mislead us and draw away our attention from some imminent areas of concern.

The district-level estimates are found to be absolutely necessary for a complete understanding of the level of living prevailing in any part of the country. The other major observations are as mentioned below.

(1) Ogive analysis was made to graphically represent the interstate disparity in distribution against a fixed set of MPCE percentile classes as also to indicate that some of the states have very little representation in the extreme end all-India MPCE classes. At sub-state level, the problem gets aggravated with the district-level distributions being farther away from the central ogive. There were 425 instances in rural India and 558 in the urban, where one or more of the all-India MPCE percentile classes did not have any representation from a particular district. The problem can be addressed through the use of state-level percentile classes. This paper suggests that in addition to the all-India MPCE percentile classes, useful for country level analysis and interstate comparisons, state-level MPCE percentile classes be used for more realistic analysis at the state and sub-state level. Although there is no precondition that state-level MPCE classes would have to be identical to the all-India MPCE classes i.e., at 5%, 10%, 20% ... 80%, 90%, 95% annexure, etc, it was only for better comparability with the official results that an identical composition of state level percentile classes has been made.

(2) In rural India at the state-level, there has been an indication of a trade-off between prosperity and inequality with rich states having high level of inequality as against a low Lorenz ratio in the poor states. But the situation is a lot more complicated in the urban sector where many of the poor states also suffer from high level of inequality.

(3) In urban India, in about half of the states, RSE of average MPCE estimate at state-level was more than 5% while in the rural

sector almost all the states had RSE less than 5% or so.

(4) There has been an intense rural-urban divide even at the district-level but the pattern has not been very predictable in either of the sectors. A district with excellent indicators in terms of any of the parameters under study in one sector often failed to perform at the same level in the other sector.

(5) From the district-level estimates of average level of living, poverty and inequality we find that the range of disparity at the sub-state level within a state was often more serious than the disparity between the states. Thus there was wide spatial disparity in the level of living of the Indian districts, both within and across the states.

(6) In both the sectors, in almost all the states, there were some districts with higher within district inequality as compared to the level of inequality at the state-level.

(7) The mapping of poverty across the districts of 20 major states enables easy identification of the pockets of critical poverty which require urgent focused attention. This also adequately reveals the grim urban poverty scenario in spite of high average urban level of living.

(8) There was adequate evidence of concentration of affluence or poverty in certain pockets of the country depicting polarisation in the level of living across the districts within the states.

(9) For about a quarter of the rural districts and in more than half of the urban districts the RSE of average MPCE was higher than 10%. But that need not deter us from using these sub-state level natural estimates adequately supported by the sample design, for in-depth analysis of within state variability. Further effective improvement can be made in these estimates through "model assisted" as well as "model independent" procedures. Developing the greg using these initial estimates and their RSE is a simple and viable option.

(10) In the NSS 2004-05 survey, in a good number of cases, low sample size resulted in high RSE of the district-level estimates especially in the urban sector. The number of sample observations needs to be suitably augmented in the future surveys, to arrive at more reliable and conclusive district-level estimates.

## NOTES

- The two-stage stratified sampling design followed in NSS surveys prior to its 61st round (2004-05) did not use districts as strata in the urban sector and thus allowed generation of unbiased estimates of population parameters at most at NSS region level.
- In the Ogive Analysis the cumulative proportions of persons per 1,000 in each state had been plotted against the MPCE cut-off points for the (12) all-India percentile classes on unequal scale.
- Usually, 12 MPCE classes (corresponding to 5%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95% and 100%) are formed for the country as a whole from the distribution of persons by MPCE separately for rural and urban sectors. This paper examines the need for undertaking similar exercise at state level for obtaining state-specific percentile classes.
- Average MPCE at national or state (or region) level is the aggregate consumer expenditure of the relevant population divided by the corresponding population.

- HCR is the ratio of population below poverty line and the total population of a particular region (i.e., proportion of population with MPCE less than the specified poverty line). The official poverty lines for India and its states are based on a calorie norm of 2,400 calories per capita per day for rural areas and 2,100 calories per capita per day for urban areas. State wise poverty lines (2004-05) used here were released by the Planning Commission in its press note in March 2007.
- The Lorenz Ratio has been obtained from the cumulated expenditure share of each MPCE class in the aggregate consumer expenditure against the cumulated population shares of these MPCE classes. The term LR-S has been used here to denote the Lorenz ratio computed for each of the major states or its districts using the state-specific MPCE percentile classes.
- Two districts of Jammu and Kashmir (Leh and Kargil) were out of survey coverage in 2004-05. In three more districts (Doda, Poonch and

Rajouri) survey could not be conducted due to insurgency problem.

- The estimates from 61st round for CES were generated using the formula as given below  
First Stage Unit (FSU): village for rural area and urban block for urban area.  
s = subscript for s-th stratum, t = subscript for t-th sub-stratum, m = subscript for sub-sample (m = 1, 2), i = subscript for i-th FSU [village/block], j = subscript for j-th second stage stratum in an FSU/hamlet group(hg)/sub-block(sb) (j=1, 2 or 3), k = subscript for k-th sample household under a particular second stage stratum within an FSU/ hg/sb  
D = total number of hg's/sb's formed in the sample village/block  
D\* = 1 if D = 1  
= D/2 for any FSUs (village/urban block) with D > 1  
Z = total size of a rural sub-stratum (= sum of sizes for all the FSUs of a rural sub-stratum), z = size of

sample village used for selection, N = total no of urban blocks, n = number of sample village/ blocks surveyed, H = total number of households listed in a second-stage stratum of a village/ block/hamlet-group/sub-block of sample fsu, h = number of households surveyed in a second-stage stratum of a village/block/hamlet-group/sub-block of sample fsu for a particular schedule.

For Rural:

$$\hat{Y} = \sum_s \sum_r \frac{1}{2} \sum_m \sum_j \frac{Z}{h_j} \sum_{i=1}^{n_j} D_i^* \left[ \frac{H_{1j}}{h_{1j}} \sum_{k=1}^{h_{1j}} y_{1jk} + \frac{H_{2j}}{h_{2j}} \sum_{k=1}^{h_{2j}} y_{2jk} \right]$$

For Urban:

$$\hat{Y} = \sum_s \sum_r \frac{1}{2} \sum_m \sum_j \frac{N}{n_j} \sum_{i=1}^{n_j} D_i^* \left[ \frac{H_{1j}}{h_{1j}} \sum_{k=1}^{h_{1j}} y_{1jk} + \frac{H_{2j}}{h_{2j}} \sum_{k=1}^{h_{2j}} y_{2jk} \right]$$

Ratio estimate ( $\hat{R}$ ) of the ratio ( $R = \frac{Y}{X}$ ) will be obtained as  $\hat{R} = \frac{\hat{Y}}{\hat{X}}$ .

- 9 Estimates of RSE for a Ratio Estimator ( $\hat{R}$ ) for stratum 's':

$$M\hat{S}E_s(\hat{R}) = \Sigma \frac{1}{4} [(\hat{Y}_{s1t1} - \hat{Y}_{s1t2})^2 + \hat{R}^2(\hat{X}_{s1t1} - \hat{X}_{s1t2})^2 - 2\hat{R}(\hat{Y}_{s1t1} - \hat{Y}_{s1t2})(\hat{X}_{s1t1} - \hat{X}_{s1t2})]$$

where  $\hat{Y}_{s1t1}$  and  $\hat{Y}_{s1t2}$  are the estimates for sub-sample 1 and sub-sample 2, respectively, for

stratum 's' and sub-stratum 't' and ( $\hat{R}$ ) is a ratio estimator. And

$$R\hat{S}E(\hat{R}) = \frac{\sqrt{M\hat{S}E(\hat{R})}}{\hat{R}} \times 100$$

- 10 For detail estimation procedures for CES (2004-05) and CES (1999-2000) one may visit www.mospi.gov.in and see NSS report No 508 on Level and Pattern of Consumer Expenditure, 2004-05.
- 11 Generalised Regression Estimate (greg) is a synthetic regression method, which involve estimating the common regression coefficient using survey data coming from each sub-domain (district) in a domain (state). The GREG estimate of simple form can be as follows. For  $d$ th district the GREG estimate is  $t_{gd} = 1/2 * (t_g(1) + t_g(2))$  with  $t_g(m) = t_m(y) + b_q(m) (X - t_m(x))$  and where  $m$  denotes the subsample and  $t_m(y)$  is the estimator for  $m$ th subsample,  $b_q$  is the regression coefficient and  $q$  assumes a suitable form of inclusion probability,  $X$  is the suitably chosen auxiliary variable.
